As discussed in previous blog posts that can be made in a very very way. The sample project code has been updated to implement the changes presented in this post. It uses a Swagger file loaded into an S3 bucket: AWSTemplateFormatVersion: '2010-09-09' Transformation: AWS::Serverless-2016-10-31 Parameters: S3BucketName: Type: String Description: The name of S3 bucket in which the Swagger specification is stored StageName: Type: String Description: The name of the stage, for example, "dev", "preprod", "prod" Default: dev Resources: Restapi: Type: AWS::Serverless::Api Properties: Name: Fn::Sub: todo-app-api-\${StageName} StageName: Ref: StageName DefinitionBody: Fn::Transform: Name: AWS::Include Parameters: Location: Fn::Join: - '/' - Ref: S3BucketName - '/swagger.yaml' In this example, the name of the S3 bucket in which the Swagger file is stored is provided as parameter for the model. He is dynamically referenced replacing the \${AWS:Region} and \${ListTasksFunction.Arn} variables with the actual values created during the creation of the CloudFormation stack launched from the SAM model that uses this Swagger file. When requests are successful, an array of Task objects © returned in JSON format. This way, © multiple instances of the same API provisioned in the same AWS account and region. First, the Swagger file presented above © modified to reference the appropriate Lambda function to handle incoming requests to the API endpoint. There are a lot of tools available to deal with this task. Again, generating documentation can be part of the CI/CD pipeline to ensure that documentation reflects the current state of the API. Therefore, it must be configured to handle events coming from the specific instance of the API Gateway endpoint. This is © required to dynamically reference the correct AWS region and RNA of Lambda function when API is © provisioned. In this way, API Gateway can be configured to osem onsem od This is used to generate documentation and therefore ensures consistent visualization on the real capabilities of a service. Going back to the configuration of compilation displayed on the blog posting a CI / CD channel without server for Sam, it can be done in the Post_build phase of the CodeBuild project, shortly before the application is packaged for implantation f o. In addition, it can also define the actual data structures consumed and returned by the own API. To perform these substitutions, the Gateway API feature must be configured on the SAM model. Configure an endpoint in the arroqance The format to describe the APIs with the swagger is JSON or YAML. In addition, the name of the stage is also provided as a parameter. Finally, the lambda function should be linked to the endpoint of the API gateway. Instead of simply referring to the arroqance file for the definition property of the RESTAPI feature, an FN : Transform is applied to it. In this way, it is possible that the CloudFormation preases the arroqance file before using it to configure the API gateway. For this, the custom X-Amazon-Apiigeway-Integration extensions is used: OpenAPI: "3.0.1" Information: Tasting: "Tasks-API" Version: "V1.0" Paths: /: Get: Summary: Task List Description: Returns List Task Answers: 200: Description: "OK" Content: Application / JSON: Scheme: Type: Matrix: \$ ref: "# / components / schemas / task / 2015-03-31 / functions / \$ (LISTTASKSFUNCTION.ARN) / Invocement Responses: Pattern: "200" PASSTHROUGHBEHAVIOR: "When no match" HttpMethod: "Post" ContentHandling: "convert to text" Type: "AWS_PROXY" "In this case, the Lambda ListTasksFunction function must be invoked for each API achievement request.
